Mapping Class Groups

S_g orientable surface, genus g

$$\begin{aligned} \text{Mod}(S_g) &:= \pi_0 \text{Diff}^+(S_g) \\ &= \text{Diff}^+(S_g) / \text{Diff}_0(S_g) \end{aligned}$$

- Examples

$$\text{Mod}(S^2) = 0$$

$$\text{Mod}(T) = SL(2, \mathbb{Z})$$

- Generated by Dehn twists

- Marked points: $\text{Mod}(S_g; k) = \pi_0 \text{Diff}^+(S_g; k)$

where $\text{Diff}^+(S_g; k) =$ diffeo's fixing a set $\{x_1, \dots, x_k\}$

Nielsen Realization Problem

$$\begin{array}{ccc} & & \text{Diff}^+(S_g) \\ & \nearrow & \downarrow p \\ (\text{finite}) \quad G & \xrightarrow{i} & \text{Mod}(S_g) \end{array}$$

[Kerckhoff '83] Every finite subgp. of $\text{Mod}(S_g)$ can be realized as a gp. of isometries for some hyperbolic structure on S_g .

- $\text{Mod}(S_g)$ acts on the Teichmüller space $\mathcal{T}_g = \mathbb{R}^{6g-6}$,
 $\mathcal{T}_g / \text{Mod}(S_g) =$ moduli space of Riemann surfaces

[K. '83] Every fin. subgp. of $\text{Mod}(S_g) \subset \mathcal{T}_g$ has a fixed point.

Case of marked points: $\mathcal{T}_k(S_g)$ is defined in a similar way

[Wolpert '87, Masur-Wolf '02] Every finite subgroup of $\text{Mod}^\pm(S_g; k)$ acting on $\mathcal{T}_k(S_g)$ has a fixed point.

Non-orientable surfaces: $N_g = \underbrace{\mathbb{R}P^2 \# \dots \# \mathbb{R}P^2}_g$

$$\text{Mod}(N_g; k) := \text{Diff}(N_g; k) / \text{Diff}_0(N_g; k)$$

Examples: $\text{Mod}(N_2) = \mathbb{Z}/2 \times \mathbb{Z}/2$, $\text{Mod}(N_3) = GL(2, \mathbb{Z})$.

Theorem (Colin, X.) Every finite subgroup $G \subseteq \text{Mod}(N_g; k)$ acting on $\mathcal{T}_k(N_g)$ has a fixed point.

$$\begin{array}{ccc}
 & \text{Diff}(N_g) & \\
 & \nearrow & \downarrow p \\
 G & \xrightarrow{i} & \text{Mod}(N_g)
 \end{array}
 \quad \begin{array}{c}
 \curvearrowright \#s \\
 \end{array}$$

Theorem (Colin, X.) If $g \geq 35$, the projection $p: \text{Diff}(N_g) \rightarrow \text{Mod}(N_g)$ does not have a section.

Klein Surfaces

For $f : U \subset \mathbb{C} \rightarrow \mathbb{C}$, $\partial_z f = \frac{1}{2}(\partial_x f - i\partial_y f)$

$$\partial_{\bar{z}} f = \frac{1}{2}(\partial_x f + i\partial_y f)$$

- f is analytic if $\partial_{\bar{z}} f = 0$
- f is antianalytic if $\partial_z f = 0$
- f is dianalytic if $f|_V$ to any connected comp. is either one.

Definition: A *Klein surface* (Σ, \mathfrak{X}) is a connected surface Σ together with a **dianalytic structure** \mathfrak{X} , (i.e. an equivalence class of dianalytical atlases).

$\mathcal{M}(\Sigma)$ = set of dianalytic structures of Σ that agree with the smooth structure.

Definition:

- A *morphism (or dianalytic map)* $f : (\Sigma, \mathfrak{X}) \rightarrow (\Sigma', \mathfrak{Y})$ is a map s.t. $\forall x \in \Sigma$ there are charts $x \in U, f(x) \in V$ with

$$\psi \circ f \circ \phi^{-1} : \phi(U) \rightarrow \psi(V) \quad \text{dianalytic}$$

- For $f \in \text{Diff}(\Sigma), \mathfrak{X} \in \mathcal{M}(\Sigma)$, the *pullback* $f^* \mathfrak{X}$ is the unique structure such that

$$f : (\Sigma, f^* \mathfrak{X}) \rightarrow (\Sigma, \mathfrak{X}) \quad \text{is a morphism.}$$

Definition: An **orientable double cover** of a non-orientable Klein surface (Σ, \mathfrak{X}) is a Riemann surface (S, \mathfrak{X}^0) with

- a dianalytic map $\pi : (S, \mathfrak{X}^0) \rightarrow (\Sigma, \mathfrak{X})$ unramified double cover
- an antianalytic involution $\sigma : S \rightarrow S$ such that $\pi \circ \sigma = \pi$.

Compact case:

$$\begin{array}{ccc} S_{g-1} & \xrightarrow{\sigma} & S_{g-1} \\ & \searrow \pi & \swarrow \pi \\ & N_g & \end{array}$$

$$N_g = S_{g-1} / \langle \sigma \rangle$$

Remark: Every $f \in \text{Diff}(N_g; k)$ admits exactly two liftings $S_{g-1} \rightarrow S_{g-1}$, one of which preserves orientation

$$\tilde{f} \in \text{Diff}^+(S_{g-1}; 2k)$$

This choice induces

$$\begin{array}{ccc} \text{Diff}(N_g; k) & \xrightarrow{\rho} & \text{Diff}^+(S_{g-1}; 2k) \\ \downarrow & & \downarrow \\ \text{Mod}(N_g; k) & \xrightarrow{\phi} & \text{Mod}(S_{g-1}; 2k) \end{array}$$

Theorem (Hope-Tillmann; Gonçalves-Guaschi-Maldonado)

1. If $g \geq 3$, $\phi : \text{Mod}(N_g) \rightarrow \text{Mod}(S_{g-1})$ is injective.
2. If $k \geq 1$, $\phi : \text{Mod}(N_g; k) \rightarrow \text{Mod}(S_{g-1}; 2k)$ is injective $\forall g$.

Teichmüller Space

Definition: $\mathfrak{X}, \mathfrak{Y} \in \mathcal{M}(\Sigma)$ are *Teichmüller equivalent* if there is $f \in \text{Diff}_0(\Sigma; k)$ such that $f : (\Sigma, \mathfrak{X}) \rightarrow (\Sigma, \mathfrak{Y})$ is a morphism.

Teichmüller space:

$$\mathcal{T}_k(\Sigma_g) = \mathcal{M}(\Sigma_g) / \text{Diff}_0(\Sigma_g; k) \approx \begin{cases} \mathbb{R}^{6g-6+2k} & \text{orientable} \\ \mathbb{R}^{3g-3+2k} & \text{non-orientable} \end{cases}$$

Lemma: For $\pi : S_{g-1} \rightarrow N_g$ orientable double cover of a non-orientable Klein surface N_g ,

1. The map $\pi^* : \mathcal{T}_k(N_g) \rightarrow \mathcal{T}_{2k}(S_{g-1})$ is injective

$$\begin{aligned} \pi^* : \mathcal{T}_k(N_g) &\rightarrow \mathcal{T}_{2k}(S_{g-1}) \\ [\mathfrak{X}] &\longmapsto [\pi^* \mathfrak{X}] \end{aligned}$$

2. The image of π^* is

$$\begin{aligned} \pi^*(\mathcal{T}_k(N_g)) &= \{[\mathfrak{X}] \in \mathcal{T}_{2k}(S_{g-1}) \mid [\sigma^* \mathfrak{X}] = [\mathfrak{X}]\} \\ &=: \mathcal{T}_{2k}(S_{g-1})_{\sigma^*} \end{aligned}$$

Nielsen Realization Theorem

- Have injections

$$\phi : \text{Mod}(N_g; k) \rightarrow \text{Mod}(S_{g-1}; 2k)$$

$$\pi^* : \mathcal{T}_k(N_g) \longrightarrow \mathcal{T}_{2k}(S_{g-1})$$

- $\text{Mod}(N_g; k)$ acts on $\mathcal{T}_k(N_g)$ by pullbacks.

Lemma: For $[\mathfrak{X}] \in \mathcal{T}_k(N_g)$ and $\alpha \in \text{Mod}(N_g; k)$

$$\pi^* (\alpha \cdot [\mathfrak{X}]) = \phi(\alpha) \cdot \pi^* [\mathfrak{X}]$$

Theorem (Colin, X) Every finite group $G \subseteq \text{Mod}(N_g; k)$ acting on $\mathcal{T}_k(N_g)$ has a fixed point.

Proof:

Let $H \subseteq \text{Mod}^\pm(S_{g-1}; 2k)$ be the subgp generated by $\phi(G)$ and $[\sigma]$.

$$\Rightarrow H \cong G \times \mathbb{Z}/2 \subseteq \text{Mod}^\pm(S_{g-1}; 2k)$$

- [Wolpert] $\Rightarrow \exists [\mathfrak{Y}] \in \mathcal{T}_{2k}(S_{g-1})$ fixed by H

$$\text{In particular } [\sigma] \cdot [\mathfrak{Y}] = [\sigma^* \mathfrak{Y}] = [\mathfrak{Y}]$$

$$\Rightarrow [\mathfrak{Y}] = \pi^*[\mathfrak{X}] \quad \text{for some } [\mathfrak{X}] \in \mathcal{T}_k(N_g)$$

- Thus, $\forall \alpha \in G$

$$\begin{aligned} \pi^*(\alpha \cdot [\mathfrak{X}]) &= \phi(\alpha) \cdot \pi^*[\mathfrak{X}] \\ &= \pi^*[\mathfrak{X}] \end{aligned}$$

$$\pi^* \text{ monomorphism} \Rightarrow \alpha \cdot [\mathfrak{X}] = [\mathfrak{X}] \quad \square$$

Non-existence of sections

Question: What about infinite subgroups of $Mod(N_g)$?
In particular,

$$p: \text{Diff}(N_g) \longrightarrow \text{Mod}(N_g)$$

$\xleftarrow{\exists s?}$

Use characteristic classes:

For $\xi: E \rightarrow B$ smooth (orientable) surface bundle,

- $T_v E =$ vertical bundle $= \ker\{d\xi: TE \rightarrow TB\}$
- $T_v E =$ 2-dim oriented vector bundle $/E$

$$e \in H^2(E; \mathbb{Z}) \quad \text{Euler class}$$

Definition: (Miller-Morita-Mumford classes for ξ)

$$\kappa_n(\xi) := \xi_1(e(T_v E)^{n+1}) \in H^{2n}(B; \mathbb{Z})$$

where $\xi_1: H^*(E; \mathbb{Z}) \rightarrow H^{*-2}(B; \mathbb{Z})$ is the *umkehr map*.

Universal bundle:

$$\begin{array}{ccc} S_g & \xlongequal{\quad} & S_g \\ \downarrow & & \downarrow \\ E_g & \longleftarrow & E \\ \downarrow & & \downarrow \\ B \operatorname{Diff}^+(S_g) & \longleftarrow & X \end{array}$$

Have classes:

$$\kappa_n \in H^{2n}(B \operatorname{Diff}^+(S_g); \mathbb{Z}) = H^{2n}(\operatorname{Mod}(S_g); \mathbb{Z}) \quad (g \geq 2)$$

Theorem (Miller, Morita, Harer)

$$\mathbb{Q}[\kappa_1, \kappa_2, \dots] \longrightarrow H^*(\operatorname{Mod}(S_g); \mathbb{Q})$$

which is an iso in the stable range $* \leq \frac{2}{3}(g-1)$.

Becker-Gottlieb transfer: $\text{trf}_\xi : \Sigma^\infty B_+ \rightarrow \Sigma^\infty E_+$

$$\begin{array}{ccccc} H^*(B) & \xrightarrow{\xi^*} & H^*(E) & \xrightarrow{\text{trf}_\xi^*} & H^*(B) \\ & \searrow & & \nearrow & \\ & & & \cdot \chi(F) & \end{array}$$

Oriented case: $\text{trf}_\xi^*(x) = \xi_!(x \cup e(T_v E))$
 $\Rightarrow \kappa_n(\xi) = \text{trf}_\xi^*(e(T_v E)^n)$

and in particular

$$\kappa_{2n}(\xi) = \text{trf}_\xi^*(p_1(T_v E)^n)$$

p_1 = first Pontryagin class

Non-oriented case: $\eta : E \rightarrow B$ non-oriented surface bundle

$$\zeta_i(\eta) := \text{trf}_\eta^*(p_1(T_v E)^i) \in H^{4i}(B; \mathbb{Z})$$

Universal bundle:

$$\begin{array}{ccc} N_g & \xlongequal{\quad} & N_g \\ \downarrow & & \downarrow \\ E_g & \longleftarrow & E \\ \downarrow & & \downarrow \\ B \operatorname{Diff}(N_g) & \longleftarrow & X \end{array}$$

Have classes:

$$\zeta_i \in H^{4i}(B \operatorname{Diff}(N_g); \mathbb{Z}) = H^{4i}(\operatorname{Mod}(N_g); \mathbb{Z}) \quad (g \geq 3)$$

Theorem (Wahl; Galatius-Madsen-Tillmann-Weiss)

$$\mathbb{Q}[\zeta_1, \zeta_2, \dots] \longrightarrow H^*(\operatorname{Mod}(N_g); \mathbb{Q})$$

which is iso in the stable range $* \leq \frac{g-3}{4}$.

$$\Rightarrow \zeta_i \neq 0 \quad \text{in} \quad H^{4i}(-; \mathbb{Q}) \quad \text{if} \quad g \geq 16i + 3$$

Theorem (Colin, X.) If $g \geq 35$, the projection $p: \text{Diff}(N_g) \rightarrow \text{Mod}(N_g)$ does not have a section.

[**Lemma:** If $p: \text{Diff}_\delta(N_g) \rightarrow \text{Mod}(N_g)$, then $p^*(\zeta_i) = 0$ in $H^{4i}(\text{Diff}_\delta(N_g); \mathbb{Q})$ for $i \geq 2$.]

Proof: If there was a section

$$\begin{array}{ccc}
 \text{Diff}_\delta(N_g) & H^*(\text{Diff}_\delta(N_g); \mathbb{Q}) & \\
 \downarrow p \quad \curvearrowright s & \begin{array}{c} \uparrow p^* \quad \downarrow s^* \\ H^*(\text{Mod}(N_g); \mathbb{Q}) \end{array} & s^* p^*(\zeta_i) = \zeta_i \neq 0 \\
 \text{Mod}(N_g) & & \\
 & & g \geq 16i + 3
 \end{array}$$

For $i = 2$, $\zeta_2 \neq 0$ if $g \geq 16(2) + 3 = 35$,

but by the Lemma $p^*(\zeta_i) = 0$ for $i \geq 2$. \square

Farrell Cohomology

Definition: Let Γ gp with $n = vcd(\Gamma) < \infty$, M any Γ -module

$$\widehat{H}^*(\Gamma; M) := H^*(\text{Hom}_{\Gamma}(\widehat{P}; M))$$

- $\widehat{H}^i(\Gamma; M) = H^i(\Gamma; M)$ for $i > n$.
- $\widehat{H}^i(\Gamma; M) = 0$ if Γ is torsion-free.
- $\widehat{H}^i(\Gamma; M)$ are torsion groups

$$\widehat{H}^*(\Gamma; \mathbb{Z}) \cong \prod_p \widehat{H}^*(\Gamma; \mathbb{Z})_{(p)}$$

- Γ has p -periodic cohomology if $\widehat{H}^i(\Gamma; \mathbb{Z})_{(p)} \cong \widehat{H}^{i+d}(\Gamma; \mathbb{Z})_{(p)}$
- **Brown's Formula:**

$$\widehat{H}^*(\Gamma; \mathbb{Z})_{(p)} \cong \prod_{\mathbb{Z}_p \in \mathcal{S}} \widehat{H}^*(N(\mathbb{Z}_p); \mathbb{Z})_{(p)}$$

Let Γ gp. of finite *vdc* and $\pi \leq \Gamma$ of odd prime order p .

$$\begin{array}{ccccccc}
 1 & \longrightarrow & \Delta & \longrightarrow & \Gamma & \longrightarrow & \Gamma/\Delta & \longrightarrow & 1 \\
 & & & & \uparrow & & \uparrow & & \\
 & & & & \pi & \xrightarrow{\cong} & \pi & &
 \end{array}$$

$$H^*(\pi; \mathbb{F}_p) = E[x_1] \otimes \mathbb{F}_p[u_2]$$

$$H^*(\Gamma; \mathbb{Z}) \longrightarrow H^*(\pi; \mathbb{Z}) \xrightarrow{\text{mod } p} \mathbb{F}_p[u] \subseteq H^*(\pi; \mathbb{F}_p)$$

- \exists a max. $m = m(\pi, \Gamma)$ such that

$$\text{im}\left(H^k(\Gamma; \mathbb{Z}) \rightarrow H^k(\pi; \mathbb{Z})\right) \subseteq \mathbb{F}_p[u^m] \subseteq H^*(\pi; \mathbb{F}_p)$$

- If Γ p -periodic gp, then p -period is given by

$$p(\Gamma) = \text{l.c.m.}\{2 \cdot m(\pi, \Gamma) \mid \pi \leq \Gamma \text{ order } p \}$$

Theorem (Colin, X.) Let $g > 2$, p odd prime. If $\text{Mod}(N_g; k)$ contains p -torsion, then the p -period is 4.

Idea of Proof:

$$\begin{array}{ccc}
 GL_2^+(\mathbb{R}) & \longrightarrow & GL_2(\mathbb{R}) \\
 \uparrow & & \uparrow \\
 \text{Faithful rep.} & & \\
 \tilde{\pi} \hookrightarrow & \longrightarrow & \text{Diff}(N_g; 1) \\
 \downarrow \cong & & \downarrow \\
 \pi \hookrightarrow & \longrightarrow & \text{Mod}(N_g; 1)
 \end{array}$$

$$\begin{array}{c}
 df_{x_0} : T_{x_0} N_g \rightarrow T_{x_0} N_g \\
 \uparrow \\
 f
 \end{array}$$

$$\begin{array}{ccc}
 c^2 & & \\
 c & H^* BGL_2^+(\mathbb{R}) & \longleftarrow & H^* BGL_2(\mathbb{R}) & p_4 \\
 \downarrow \text{First Chern class} & \downarrow & & \downarrow & \\
 0 \neq v & H^*(B\tilde{\pi}) & \longleftarrow & H^* B \text{Diff}(N_g; 1) & \\
 \uparrow \cong & \uparrow & & \uparrow & \\
 H^*(B\pi) & \longleftarrow & H^* B \text{Mod}(N_g; 1) & & \\
 0 \neq \bullet & & & & \bullet
 \end{array}$$

The diagram shows a commutative square of cohomology groups. The top row is $H^* BGL_2^+(\mathbb{R}) \leftarrow H^* BGL_2(\mathbb{R})$ with a red c^2 above the first term and a red p_4 above the second. The bottom row is $H^*(B\pi) \leftarrow H^* B \text{Mod}(N_g; 1)$ with a red $0 \neq \bullet$ below the first term and a red \bullet below the second. The left vertical arrow is labeled "First Chern class" and points from $H^* BGL_2^+(\mathbb{R})$ to $H^*(B\pi)$. The right vertical arrow is labeled \cong and points from $H^* B \text{Diff}(N_g; 1)$ to $H^* B \text{Mod}(N_g; 1)$. The middle horizontal arrow is labeled \cong and points from $H^*(B\tilde{\pi})$ to $H^* B \text{Diff}(N_g; 1)$. Two curved arrows connect the right side of the top row to the right side of the bottom row: one from p_4 to \bullet and one from \bullet to $0 \neq \bullet$.

Fixed point data

Fixed point data for diffeo's: Let $\phi \in \text{Diff}^+(S_g)$ of order p ,

$$\langle \phi \rangle = \mathbb{Z}/p \curvearrowright S_g$$

- $\text{Sing}(\langle \phi \rangle) = \{x_i\} =$ (finite) set of fixed points
- ϕ acts by rotation on $T_{x_i}(S_g)$ wrt a fixed RS structure
- Let $0 < \beta_i < p$ s.t. ϕ^{β_i} acts by mult. by $e^{2\pi i/p}$

$$\delta(\phi) := (\beta_1, \dots, \beta_t)$$

- [Nielsen] ϕ_1, ϕ_2 of order p , conjugated $\Leftrightarrow \delta(\phi_1) = \delta(\phi_2)$.
- [Symonds] $\delta(\phi)$ depends only on the isotopy class of ϕ .

So, for $[\phi] \in \text{Mod}(S_g)$ $\delta([\phi]) := (\beta_1, \dots, \beta_t)$

- $[\phi_1], [\phi_2] \in \text{Mod}(S_g)$ conjugated $\Leftrightarrow \delta([\phi_1]) = \delta([\phi_2])$.

Non-orientable case: For $\phi \in \text{Diff}(N_g)$ of order p

$$\delta(\phi) := (\beta_1, \dots, \beta_t)$$

- Well defined up to sign.
- $\delta(\phi) \cong \delta(\phi') \Leftrightarrow (\beta_1, \dots, \beta_t) = (\varepsilon_1 \beta'_1, \dots, \varepsilon_t \beta'_t), \quad \varepsilon_i = \pm 1$

Non-orientable case, marked points: For $\phi \in \text{Diff}(N_g; k)$ of order p

$$\delta_k(\phi) := (\beta_1, \dots, \beta_k \mid \beta_{k+1}, \dots, \beta_t)$$

where

- $(\beta_1, \dots, \beta_k)$ ordered k -tuple, fixed point data of marked points.
- $(\beta_{k+1}, \dots, \beta_t)$ unordered $(t - k)$ -tuple.
- Similar \cong notion.
- Well defined on $\text{Mod}(N_g)$ and $\text{Mod}(N_g; k)$.
- $[\phi_1], [\phi_2] \in \text{Mod}(S_g; k)$ conjugated $\Leftrightarrow \delta_k([\phi_1]) = \delta_k([\phi_2])$.

Theorem (Colin, X.)

1. $Mod(N_g; k)$ contains a subgroup of order p if and only if the Riemann-Hurwitz equation

$$g - 2 = p(h - 2) + t(p - 1)$$

has an integer solution with $t \geq k$, $h \geq 1$.

2. For all $g > 2$ and odd prime p , if $Mod(N_g; k)$ has p -torsion then it has p -periodic cohomology.

Theorem Let $g > 2$, $k \geq 1$ and $t > 1$ an integer satisfying the equation

$$g - 2 = p(h - 2) + t(p - 1),$$

then,

$$\left\{ \begin{array}{l} \text{Congruence classes of } t\text{-tuples} \\ (1, \beta_2, \dots, \beta_k \mid \beta_{k+1}, \dots, \beta_t) \\ \text{with } 0 < \beta_j < p \end{array} \right\} \leftrightarrow \left\{ \begin{array}{l} \text{Conjugacy classes of order } p \\ \text{subgps of } Mod(N_g, k) \text{ acting} \\ \text{on } N_g \text{ w/ } t \text{ fixed points} \end{array} \right\}$$

Example: Case $g = p$

Only solution: $(h, t) = (1, 2)$

Theorem: Let $\mathbb{Z}_p \leq \text{Mod}(N_p; k)$, with $k = 1, 2$. Then $N(\mathbb{Z}_p) \cong D_{2p}$ and thus

$$\widehat{H}^i(N(\mathbb{Z}_p); \mathbb{Z})_{(p)} = \begin{cases} \mathbb{Z}_p & i \equiv 0 \pmod{4} \\ 0 & i \equiv 1, 2, 3 \pmod{4}. \end{cases}$$

Theorem: Let p be an odd prime. Then, for $k = 1, 2$

$$\widehat{H}^i(\text{Mod}(N_p, k); \mathbb{Z})_{(p)} = \begin{cases} (\mathbb{Z}_p)^{\frac{p-1}{2}} & i \equiv 0 \pmod{4} \\ 0 & i \equiv 1, 2, 3 \pmod{4}. \end{cases}$$
